Product Analysis Report for Fintech Investment App

Overview

This report summarises user behaviour and product performance for a mobile-first investment app based on a simulated event dataset and accompanying Power BI dashboard (Dashboard_AZ.pbix). Users sign up, link their bank, fund the account and make an investment. Revenue is driven by active investors, so understanding the funnel, cohort quality and experiment impact is critical.

Funnel Performance

- **Strong sign-up conversion:** All 10 000 registered users opened the app. Over 93 % completed sign-up and 64 % linked their bank. These high completion rates suggest low friction in the early onboarding experience.
- **Funding bottleneck:** Only 3 204 users funded their account, corresponding to a conversion of **32 %** from app open to funded. This step showed the steepest drop-off—roughly half of bank-linked users never funded—indicating significant friction or hesitancy at the point of depositing money.
- **Investment activation:** Of those who funded an account, around **80 %** made a first investment, resulting in 2 553 investing users. While the activation rate is healthy, the absolute number of investors remains small relative to sign-ups.
- **Channel & platform insights:** Conversions were consistent across acquisition channels (~31–34 %). A slight edge appeared for organic and social channels. Platform differences were less meaningful; however, a small number of web users showed lower conversion, likely due to sample size.

Retention & Cohort Analysis

- **Rapid early engagement:** Cohort retention averaged **83 %** in Week 1, reflecting habitual engagement immediately after sign-up. Users with an investment made within seven days exhibited marginally higher Week-1 retention (~88 %) than non-investors (~83 %).
- **Sharp decline over time:** Retention dropped to **42 %** by Week 4 and **17 %** by Week 8, indicating many users disengage after the first month. Early investors did not retain materially better at 30 days than non-investors (38 % vs 40 % 30-day retention), suggesting that simply making a first investment does not guarantee long-term usage.
- **Channel quality:** Organic and referral cohorts retained slightly better by Week 8 than paid and social cohorts, hinting that these channels bring higher-quality users. No significant differences were observed across countries or platforms.

Experiment Evaluation

A/B testing compared the existing onboarding flow (control) with a redesigned flow encouraging earlier bank linking. Results from the dashboard and SQL queries show:

- **Increased funding conversion:** Treatment users had a funded account rate of **35.2 %**, compared with **28.9 %** for control, yielding a 6.3-point uplift. A z-test confirmed statistical significance ($p < 0.001$). This increase in funded users directly addresses the main funnel bottleneck.
- **Unchanged time to invest:** The median time from sign-up to first investment remained about nine days for both variants, suggesting the redesign impacts funding behaviour without delaying or accelerating investment.
- **Neutral retention effects:** 7-day and 30-day retention rates were effectively identical across variants (about 83 % and 39 %), indicating no negative engagement trade-off from the new flow.

Key Takeaways

1. **Focus on funding friction:** The biggest opportunity is reducing drop-off at the funding step. Optimising the deposit process—simplifying bank verification, adding trust signals and offering incentives—could dramatically increase the active investor base.
2. **Scale the new onboarding flow:** The experiment demonstrates a clear uplift in funded-account conversion with no downside on retention. Rolling out the redesigned flow broadly should be a priority.
3. **Drive ongoing engagement:** Rapid early churn implies users see little reason to return after sign-up. Introducing personalised notifications, auto-invest features and goal-based portfolios could encourage repeated engagement and higher lifetime value.
4. **Refine acquisition channels:** Although differences are small, organic and referral channels show slightly better long-term retention. Marketing budgets should reflect these quality differences, with ongoing monitoring.

By addressing funding friction, scaling the successful experiment and investing in retention-driving features, the product team can convert more sign-ups into active, long-term investors, ultimately driving sustainable revenue growth.
